Helly theorem

Theorem (Helly, 1923)

Let \mathcal{F} be a finite family of convex sets in \mathbb{R}^d . If any d + 1 sets from \mathcal{F} have a non-empty intersections, then all sets from \mathcal{F} have a non-empty intersection.

Helly-type theorems	Delone sets	Crystals	Cut-and-project sets	OPEN QUESTIONS
000	00000	0000	0000	00000000

Helly-type theorem for lattices

Theorem (Doignon, 1973)

Let \mathcal{F} be a finite family of convex sets in \mathbb{R}^d . If any 2^d sets from \mathcal{F} intersect at an integer point, then all sets from \mathcal{F} intersect at an integer point.

In both theorems the numbers d + 1 and 2^d can't be decreased.

Helly number for a set

Definition

Fix a set *S* in \mathbb{R}^d .

Let *n* be the smallest integer number such that the following condition hold for any finite family \mathcal{F} of convex sets in \mathbb{R}^d . If any *n* sets from \mathcal{F} intersect at a point of *S*, then all sets from \mathcal{F} intersect at a point of *S*.

This number *n* is called the **Helly number of** *S*, or just *S*-**Helly number**, or h(S).

If a number *n* from the definition doesn't exist, then $h(S) = \infty$.

DISCRETE AND DELONE SETS

Definition

A set *S* in \mathbb{R}^d is called a **discrete set** if every ball in \mathbb{R}^d contains only finitely many points of *S*.

Definition

A set *S* in \mathbb{R}^d is called a **Delone set** if

 distance between two different points of *S* is bounded from below by a positive number;

► radius of a ball in ℝ^d without points of *S* is bounded above. Sometimes Delone sets are called separated nets which are **uniformly discrete** and **relatively dense**.

000	00000	0000	0000	00000000

Helly numbers for discrete sets

Let *S* be a discrete set in \mathbb{R}^d and n(S) be the largest number of vertices of an **empty** *S***-polytope**.

Definition

A **convex** polytope *P* is an empty *S*-polytope if

- ▶ all vertices of *P* are from *S*, and
- ▶ *P* does not contain other points from *S*.

Lemma (Hoffman, 1979)

h(S) = n(S) or $h(S) = \infty$ if n(S) does not exist.

Helly numbers for Delone sets. Finite and infinite

Example

For \mathbb{Z}^d , the unit cube $[0,1]^d$ has 2^d vertices and is empty.

Any set of at least $2^d + 1$ points from \mathbb{Z}^d contains two points from one parity class and does not give an empty \mathbb{Z}^d -polytope.

Example

For every $n \ge 3$ we can find a convex *n*-gon with vertices in the lattice \mathbb{Z}^2 . Using an appropriate $GL_2(\mathbb{Z})$ transformation we can make this polygon "very thin" (and long) lattice polygon P_n .

Placing copies of P_n "very far apart" and removing lattice points inside each P_n we get a Delone set with infinite Helly number because it contains an empty *n*-gon for every $n \ge 3$.

Discrete sets with finite Helly number

What are discrete or Delone sets with finite Helly number?

Theorem (De Loera, La Haye, Oliveros, Roldán-Pensado)

- If $S = \mathbb{Z}^2 \setminus L$ where L is a sublattice of \mathbb{Z}^2 , then $h(S) \leq 6$;
- If $S = \mathbb{Z}^d \setminus (L_1 \cup \ldots \cup L_k)$ where each L_i is a (shifted) sublattice of \mathbb{Z}^d , then $h(S) \leq C_k 2^d$.

Crystals and crystallographic groups

Definition

Crystallographic group is a discrete subgroup of isometries with bounded fundamental domain.

Definition

Crystal is a union of finitely many orbits of a crystallographic group.

Theorem (Bieberbach, 1910)

Every crystallographic group in \mathbb{R}^d contains a subgroup of finite index isomorphic to \mathbb{Z}^d .

Definition

A *k*-crystal in \mathbb{R}^d is a union of *k* translations of the same lattice.

000	00000	0000	0000	00000000

CUT-AND-PROJECT SETS, FORMAL DEFINITION

Definition

- Λ is a (d + k)-dimensional lattice in $\mathbb{R}^d \times \mathbb{R}^k$;
- W is a compact set in ℝ^k such that closure of the interior of W is W, the window;
- π_1 and π_2 are projections on \mathbb{R}^d and \mathbb{R}^k . Projection $\pi_1|_{\Lambda}$ is injective and projection $\pi_2(\Lambda)$ is dense.

Then $V = V(\mathbb{R}^d, \mathbb{R}^k, \Lambda, W) = \{\pi_1(\mathbf{x}) | \mathbf{x} \in \Lambda, \pi_2(\mathbf{x}) \in W\}$ is called a **cut-and-project set**.

$$\begin{array}{cccc} \mathbb{R}^d & \xleftarrow{\pi_1} \mathbb{R}^d \times \mathbb{R}^k \xrightarrow{\pi_2} & \mathbb{R}^k \\ \cup & \cup & \cup & \cup \\ V & \Lambda & W \end{array}$$

Helly numbers for cut-and-project sets

Theorem

If $V = V(\mathbb{R}^d, \mathbb{R}^k, \Lambda, W)$ is a cut-and-project set with convex window W, then $h(V) \leq 2^{d+k}$.

Proof.

- Suppose *P* is an empty *V*-polytope with at least 2^{d+k} + 1 vertices;
- π_1 -preimages of the vertices of *P* are points of the lattice Λ ;
- Due to Doignon's theorem, there is an additional lattice point x in the convex hull of preimages;
- Due to convexity of *W*, point $\pi_1(\mathbf{x})$ is in *V* and in *P*.
