

# Quick Sort: Array-Based Lists

- Uses the divide-and-conquer technique
  - The list is partitioned into two sublists
  - Each sublist is then sorted
  - Sorted sublists are combined into one list in such a way so that the combined list is sorted

```
if (the list size is greater than 1)
{
    a. Partition the list into two sublists, say lowerSublist and
        upperSublist.
    b. Quick sort lowerSublist.
    c. Quick sort upperSublist.
    d. Combine the sorted lowerSublist and sorted upperSublist.
}
```

# Quick Sort: Array-Based Lists (continued)

- To partition the list into two sublists, first we choose an element of the list called **pivot**
- The goal is to re-arrange the list so that the **pivot** divides the list into: `lowerSubList` and `upperSubList`
  - The elements in `lowerSubList` are  $< \text{pivot}$
  - The elements in `upperSubList` are  $\geq \text{pivot}$

FIGURE 19-38 `list` after the partition

# Quick Sort: Array-Based Lists (continued)

- Partition algorithm (we assume that `pivot` is chosen as the middle element of the list):
  - Determine `pivot`; swap it with the first element of the list
  - For the remaining elements in the list:
    - If the current element is less than `pivot`, (1) increment `smallIndex`, and (2) swap current element with element pointed by `smallIndex`
  - Swap the first element (`pivot`), with the array element pointed to by `smallIndex`

# Quick Sort: Array-Based Lists (continued)

- Step 1 determines the pivot and moves `pivot` to the first array position
- During the execution of Step 2, the list elements get arranged

# Analysis: Quick Sort

**TABLE 19-10** Analysis of the Quick Sort Algorithm for a List of Length  $n$

	<b>Number of comparisons</b>	<b>Number of swaps</b>
Average case	$(1.39)n\log_2 n + O(n) = O(n\log_2 n)$	$(0.69)n\log_2 n + O(n) = O(n\log_2 n)$
Worst case	$\frac{n^2}{2} - \frac{n}{2} = O(n^2)$	$\frac{n^2}{2} + \frac{3n}{2} - 2 = O(n^2)$
