

Objectives

- 1. Define stress, normal stress, direct shear stress, and factor of safety.
- 2. Design members subjected to an axial load while considering allowable stress.
- 3. Design members subjected to direct shear while considering allowable stress.

Saint-Venant's Principle

• "If the forces acting on a small portion of the surface of an elastic body are replaced by another statically equivalent system of forces acting on the same portion of the surface, this redistribution of loading produces substantial changes in the stresses locally, but has a negligible effect on the stresses at distances which are large in comparison with the linear dimensions of the surface on which the forces are changed." (B. Saint-Venant, Mém. savants étrangers, vol. 14, 1855.)

SHEAR STRESS IN CONNECTIONS

Factor of Safety (FS) is a ratio of the failure load,
$$F_{fail}$$
, divided by the
allowable load, F_{ailow} . (FS>1) $FS = \frac{F_{Fail}}{F_{Allow}}$ If the load applied to the member is linearly related to the stress
developed within the member, then $FS = \frac{N_{Fail}}{N_{Allow}} = \frac{\sigma_{Fail}}{\sigma_{Allow}}$ $FS = \frac{V_{Fail}}{V_{Allow}} = \frac{\tau_{Fail}}{\tau_{Allow}}$

Stress Concentration Factor

• A stress concentration factor "K" is used to determine the maximum stress at sections where the cross-sectional area changes.

$$K = \frac{\sigma_{max}}{\sigma_{avg}}$$

- K is found from graphs in handbooks of stress analysis
- + σ_{avg} is the average normal stress at the smallest cross section

Thin-Walled Pressure Vessels

- Cylindrical or spherical vessels are commonly used in industry to serve boilers or tanks.
- A "thin wall" refers to a vessel having an inner radius to wall thickness ratio of 10 or more $\left(\frac{r}{t} \ge 10\right)$.
- We will assume a uniform or constant stress distribution throughout the thickness because it is thin.
- Pressure vessels are subjected to loadings in all directions.

Spherical Vessels

$$\sigma_2 = \frac{pr}{2t}$$

- $\label{eq:stars} \begin{array}{ll} \bullet \ \sigma_{a\prime} \sigma_{a\prime} \\ and & longitudinal & directions, \\ respectively. \end{array}$
- Each is assumed to be constant throughout the wall of the cylinder, and each subjects the material to tension.
- p: the internal gauge pressure developed by the contained gas
- r: the inner radius of the cylinder
- t: the wall thickness (r/t≥10)

• The tank of the air compressor is subjected to an internal pressure of 90 psi. If the internal diameter of the tank is 22 in, and the wall thickness is 0.25 in, determine the stress components acting at point A. Draw a volume element of the material at this point, and show the results on the element.

• The A-36 steel band is 2 in wide and is secured around the smooth rigid cylinder. If the bolts are tightened so that the tension in them is 400 lb, determine the normal stress in the band, the pressure exerted on the cylinder, and the distance half the band stretches.

Objective

- 1. Define shear stress due to an internal torsional moment, polar moment of inertia, and power transmitted by a torsional shaft.
- 2. Design torsional-loaded members including noncircular shafts.

Recall: How to Determine Internal Resultant Torque

- If necessary, determine the reactions on the shaft
- Section (cut) the shaft perpendicular to its axis at the point where the shear stress is to be determined
- Draw a free-body diagram of the shaft on either side of the cut
- Use a static-equilibrium equation and the following sign convention to obtain the internal torque at the section

+6(x) +6(x) +7(x) +6(x) +7(x) +6(x) +7(x)

> Positive sign conv for T and ϕ

- Sign Convention
 - Using the right-hand rule, the torque and angle of twist will be positive, provided the thumb is directed outward from the shaft when the fingers curl to give the tendency for rotation.

Example 3

• The assembly consists of two sections of galvanized steel pipe connected together using a reducing coupling at B. The smaller pipe has an outer diameter of 0.75 in and an inner diameter of 0.68 in, whereas the larger pipe has an outer diameter of 0.86 in. If the pipe is tightly secured into the wall at C, determine the maximum shear stress developed in each section of the pipe when the couple shown is applied to the handles of the wrench.

Example 6

- The gear motor can develop 3 hp when it turns at 150 rev/min. If the allowable shear stress for the shaft is τ_{allow} =12 ksi, determine the smallest diameter of the shaft to the nearest 1/8 in that can be used.

Example 7

• The 25 mm diameter shaft on the motor is made of a material having an allowable shear stress of τ_{allow} =75 MPa. If the motor is operating at its maximum power of 5 kW, determine the minimum allowable rotation of the shaft.

MODULE 2C: NORMAL STRESS DUE TO BENDING MOMENT

Samantha Ramirez, MSE

NORMAL STRESS DUE TO BENDING MOMENT

The Flexure Formula

• Similarly,

$$\sigma = -\frac{My}{I}$$

- where y is the perpendicular distance from the neutral axis to the point of interest
- This equation is valid for beams with cross-sectional areas symmetric about the y-axis.
- Note: For linear elastic materials, the neutral axis passes through the centroid

• Determine the smallest allowable diameter of the shaft which is subjected to the concentrated forces. The sleeve bearings at A and B support only vertical forces, and the allowable bending stress is $\sigma_{\rm allow}=$ 22 ksi.

SHEAR STRESS DUE TO SHEAR FORCE

Samantha Ramirez, MSE

Transverse Shear Stress

• A beam will support both shear forces and bending moments. Due to the complementary property of shear, this stress will create corresponding longitudinal shear stresses which will act along longitudinal planes of the beam.

Shear in Straight Members

- Transverse loadings will generate both bending moments and shear forces along the beam.
- When a beam is subjected to both bending and shear, the cross section will not remain plane.
 - Assuming small cross-sectional warping allows it to be neglected.

The Shear Formula

$$\tau = \frac{VQ}{It}$$

- + $\boldsymbol{\tau}$: the shear stress in the member at the point located a distance y' from the neutral axis
- V: the internal resultant shear force
- Q: $\bar{y}'A'$, where A' is the area of the top (or bottom) portion of the member's cross-sectional area, above (or below) the section plane where t is measured, and \bar{y}' is the distance from the neutral axis to the centroid of A'
- I: the moment of inertia of the entire cross-sectional area calculated about the neutral axis
- t: the width of the member's cross-sectional area, measured at the point where $\boldsymbol{\tau}$ is to be determined

 Calculate the value of Q and t that are used in the shear formula for finding the shear stress at the point shown. Also, calculate Q_{max}.

• If the wide-flange beam is subjected to a shear of V=20 kN, determine the shear stress on the web at A. Indicate the shear-stress components on a volume element located at this point.

• If the T-beam is subjected to a vertical shear of V = 12 kip, determine the maximum shear stress in the beam. Also, compute the shear-stress jump at the flange-web junction AB. Sketch the variation of the shear-stress intensity over the entire cross section.

• The beam has a square cross-section and is made of wood having an allowable shear stress of 1.4 ksi. If it is subjected to a shear force of 1.5 kip, determine the smallest dimension a of its sides.

• The shaft is supported by a smooth thrust bearing at A and a smooth journal bearing at B. If P=26 kN, determine the absolute maximum shear and bending stress in the shaft.

• Determine the maximum shear stress and normal stress in the T-beam at the critical section where the internal shear force is maximum and internal bending moment is maximum.

• Several forces are applied to the pipe assembly. Knowing that each section of pipe has inner and outer diameters equal to 36 and 42 mm, respectively, determine the normal and shear stresses at point H located at the top of the outer surface of the pipe.
